fullDescriptionUnstructured: Estas subespecies es notablemente dicromáticas, en un extremo, el color amarillo de las alas posteriores se extiende hasta la base de las mismas, mientras que en el otro extremo de la banda discal amarilla es mucho más reducida (Rothschild-Rothschild & Jordan, 1906).

Las bandas discales de las alas anteriores, a menudo se lava con naranja por encima, como es el caso de *P. polyxenes stabilis*. Mientras que una de las hembras (Mérida) es casi tan pálida como *P. Indra.*; el último lugar de la banda es casi siempre mucho más largo que el parche M2-SM2. La base de las alas posteriores, en la mayoría de los individuos es más negra, que lejos, que SC2 o un poco más allá, pero en muchos ejemplares de la zona, la base negra es muy restringida, después de haber desaparecido prácticamente en unos pocos individuos (Rothschild-Rothschild & Jordan, 1906).

En la parte inferior del área basal de las alas posteriores, la ampliación negra se encuentra en un porcentaje restringido a la base de los extremos o se encuentra totalmente ausente, a veces en las alas anteriores es mucho mas baja la sombra de color crema. El abdomen tiene a menudo, una amplia franja lateral de color amarillo, con el cual la parte dorso-lateral de los puntos son más o menos fusionados. La barra celular de la parte post mediana de las alas anteriores es a menudo más o menos clara en la parte inferior (Rothschild-Rothschild & Jordan, 1906).

abstract: *Papilio polyxenes americanus* se encuentra en Venezuela, Colombia, Ecuador y Norte del Perú (Seitz, 1924) y presenta tres variedades. En la forma *melasina*, la banda amarilla en las alas es muy reducida, a veces reducida a un pequeño lugar (Seitz, 1924), tiene manchas azules más reducidas en las alas posteriores (Le Crom et al., 2002), mientras que en el verdadero *americanus*, la banda es amplia, especialmente en las alas posteriores de color amarillo pálido, muy pocas veces llega a la base (Seitz, 1924).
