habitatUnstructured: El Pato Media Luna es un ave migratoria que se encuentra en Colombia entre septiembre y abril, se localiza principalmente en pantanos, lagos de agua dulce, humedales, estanques y estuarios costeros (Asociación Bogotana de Ornitología, 2000; Hilty & Brown, 1986). Estos patos no pueden volar durante la muda de finales de verano, y pasan esta temporada en praderas o grandes pantanos (The Cornell Lab of Ornithology, 2014). En invierno, esta especie se puede encontrar en marismas y pantanos de agua dulce y salobre (EOL, n.d.). Los migrantes utilizan pantanos, humedales con vegetación alrededor y campos de arroz, por lo general se detienen en áreas con agua dulce o salobre en vez de agua salada. También permanecen en humedales dulces o salobres que contengan gran cantidad de vegetación y materia orgánica en descomposición (The Cornell Lab of Ornithology, 2014).

fullDescriptionUnstructured: Es un pato pequeño, tiene entre 36 y 41 cm de longitud, el peso de los machos esta alrededor de 380 g, el de las hembras 340 g (Dunning, 2008); el macho es un poco más grande que la hembra. Existe dimorfismo sexual donde el macho exhibe una media luna facial blanca distintiva ubicada delante del ojo, la cabeza es de color azul grisáceo y el manto es café oscuro fuertemente escamado con ante y las zonas inferiores más claras, se diferencia un parche blanco en el flanco, el pico es pequeño y negro, las patas anaranjadas; la hembra presenta el cuerpo moteado de café oscuro, la coronilla y lista ocular son negruzcas, presenta un punto blanco en los lores; el pico es gris oscuro y las patas amarillas. Ambos sexos presentan un parche azul pálido en la parte delantera del ala. Espéculo verde, que se observa en el vuelo, tienen ojos oscuros y cola y alas puntiagudas. Los machos llegan en el otoño con plumaje básico, como el de las hembras y adquieren el reproductivo en enero o febrero (Asociación Bogotana de Ornitología, 2000; Elizondo, 2013; Hilty & Brown, 1986). Una especie de pato emparentada cercanamente con A. discors es el pato colorado (A. cyanoptera), lo que hace que en ocasiones sea muy difícil su identificación acertada en el campo. El macho no reproductivo del pato colorado (Anas cyanoptera) es muy similar a la hembra del pato Media Luna, distinguiéndose solamente por los ojos rojos. También presenta similitudes con el pato Cucharo (Anas clypeata), en cuanto al parche alar azul observado en el vuelo, aunque este pato es de mayor tamaño y el pico es espatulado (Asociación Bogotana de Ornitología, 2000; Hilty & Brown, 1986). briefDescription:

modified: created: mimeType: dataType: identifier:

reproductionUnstructured: Las hembras buscan volando el lugar donde construirán el nido, esto puede tomarle varios días mientras los machos esperan cerca; los nidos se construyen cerca al agua y cubierto por vegetación. La hembra construye el nido raspando con sus patas para hacer una depresión circular, luego añade pastos secos que va recogiendo y luego le pone sus plumas del pecho. La vegetación se encarga de ocultar los nidos hacia los laterales y hacia arriba. El nido acabado es de unos 8 centímetros de diámetro, con un diámetro interior de aproximadamente 6 pulgadas y 2 de profundidad (The Cornell Lab of Ornithology, 2014). Las parejas se forman a finales del periodo invernal. La temporada de reproducción es entre finales de Abril y Junio y ponen entre 6 y 14 huevos color crema (Asociación Bogotana de Ornitología, 2000; Hilty & Brown, 1986).

En verano el Pato Media Luna cría en estanques poco profundos alimentándose también con insectos acuáticos como las larvas de jején, almejas y caracoles, crustáceos, algo de vegetación y granos; todos estos elementos de su dieta tienen gran importancia en la alimentación durante la
temporada de reproducción, las hembras ponedoras deben tener una dieta alta en proteínas. En invierno consumen semillas de arroz y lirios de agua (The Cornell Lab of Ornithology, 2014; EOL, n.d.).

behaviorUnstructured: Es un pato sociable de comportamiento gregario, a veces se encuentra agrupado con otras especies de patos, cuando se espanta una bandada, alzan vuelo explosivamente en forma rápida y errática. Es el

pato migratorio más abundante, para la migración utiliza preferentemente las rutas continentales en lugar de las costeras. Su vuelo es rápido y ágil. (Asociación Bogotana de Ornitología, 2000; Elizondo, 2013; Hilty & Brown, 1986). Se alimenta salpicando el agua, sumergiendo toda la cabeza o hasta alcanzar su presa, aunque rara vez se zambulle por completo. El macho tiene una gama de movimientos exagerados al igual que otros patos, en el cortejo incluye un bombeo de agua metiendo la cabeza rápidamente o chapoteando con las alas, las hembras pueden responder bajando la cabeza, apuntando al macho con el pico y luego levanta la cabeza. La pareja normalmente se disuelve durante el periodo de incubación y los adultos forman nuevos pares como compañeros durante el invierno o la primavera. Muchos machos cortejan a la misma hembra hasta que esta escoja a su pareja, en ocasiones, hay cópula forzada por machos que no son su pareja, ocurrencia común en muchas especies de patos y comparativamente rara en el Pato Media Luna (The Cornell Lab of Ornithology, 2014; EOL, n.d.).

mimeType: dataType: identifier:

distributionUnstructured: El Pato Media Luna tiene una amplia distribución, se encuentra desde Estados Unidos hasta Argentina; se han observado individuos errantes en el litoral Atlántico de Europa occidental y noroeste de África, en las Islas Galápagos y otras islas del Pacífico. Y se encuentra distribuido hasta los 3600 msnm (Asociación Bogotana de Ornitología, 2000). En Colombia se observa desde los Andes hasta el este del Meta. Se reconocen dos subespecies: Anas discors discors (Linnaeus, 1766) y Anas discors orphna (orphna Stewart & Aldrich, 1956) (ITIS, 2014), esta última migra ocasionalmente y ha sido observada en Cali. Aunque es un ave migratoria que se encuentra de paso en Colombia en la temporada invernal, se han reportado individuos que se quedan como residentes permanentes y anidan en el Humedal de la Conejera (Asociación Bogotana de Ornitología, 2000; Hilty & Brown, 1986).

abstract: El Pato Media Luna es de los más pequeños. El macho se identifica fácilmente por las grandes manchas blancas en forma de media luna en los lados de su cabeza y por su moteado en el pecho y lados del cuerpo. En otoño, cambia el plumaje y se asemeja a las hembras y jóvenes, ambos sexos tienen grandes manchas azules en las alas. Se encuentran en Estados Unidos y Canadá, y algo más al sur que otras especies de patos migratorios. En los trópicos, el Pato Media Luna también se pueden encontrar en los humedales y en ecosistemas de agua salada dominados por manglares. Pueden observarse en agua o tierra buscando alimento, realizando vuelos rápidos, en migración o en zonas de cría y alimentación. Son mas activos durante el día (EOL, n.d.).
